The ELBE Center for High Power Radiation Sources

Receiving a larger facility upgrade since 2011 [1], ELBE will soon combine its 40 MeV c.w. electron LINAC (upgraded to 1.6 mA) with two high intensity laser facilities DRACO and PENELOPHE [2] for laser driven particle acceleration and electron-laser beam interaction [3]. Due to Building expansion and new laser & radiation safety requirements, a complete redesign of the existing PSS was necessary:

- replacement of the aged out S5 based PSS in 2011
- extension for new or redesigned electron beam targets in 2012
- complete implementation for new laser target sites by end of 2013

The general building concept is to separate the accelerator or lasers from the target sites (fig. 1). Electron beam transport is possible through shutters in combination with dipole structures. Laser beams have to pass a subsurface chicane that is closed by shutters. The radiation protection caves are entered through shielding gates. Closing a room requires following a well-defined search procedure. Dose rate is measured in all monitored or controlled areas.

A New PSS for the ELBE Accelerator Facility

Table 2: PSS software main tasks

| PSS Software Implementation
|-----------------------------------------------|

The new PSS is based on two Simatic S7-317F PLCs [4] connected by failsafe communication (fig. 2). Peripheral units are:

- key panel for basic operational modes
- GUI panels for service, operation and alarms (WinCC flexible [4])
- SCADA interface (WinCC [4]) for operation, data logs, alarms
- PLC system (standard technology) for dose rate data acquisition

Safety related I/O signals use binary failsafe channels with redundancy according to the SIL requirements in closed-circuit technology. These channels are subject to monitoring for wire break, short or discrepancies.

Hardware Implementation

A detailed hazards and risks assessment was carried out following IEC 61508 [4], where the safety functions were formulated and their safety implementation level (SIL) was derived taking into account organizational requirements, a complete redesign of the existing PSS was necessary:

- Most safety functions for the electron accelerator demand SIL1 or SIL2.
- Laser related safety functions require no specific safety technology as the group of staff is small and radiation levels are comparably low with respect to the electron accelerator.

PSS Software Implementation

The safety PLCs are configured and programmed using Step7 V5.5 [5]. Safety and standard program are separated by different code areas. The safety code is executed in fixed cycle (100 ms) and is monitored for data falsification during execution. It includes all safety functions (see table 2). Unauthorized software or configuration changes will cause a CRC change and lead to loss of the approval of operation.
