Abstract

Following the cessation in the production of the commercial ADC/DAC boards adopted by the ELETTRA/SLS digital multi-bunch feedback systems, a new family of 500 MS/s data conversion boards with an 8 bit resolution has been developed. The ADC and DAC circuits are separate modules containing analog and digital electronics providing a data rate of 500 MSample/sec using 250 MHz DDR clocking techniques. The following stage being a common design to both ADC and DAC reduce the data rate to 125 MS/sec, allows data recording and play back using on board RAM and allows freely programmable multiplexing/demultiplexing up to ratios of one to twelve. The digital data streams flow via Front Panel Digital Ports (FPDP). A special design criterion were low system latencies ensuring a high feedback efficiency. Apart from lab tests, we report on feedback system test and describe additional hardware applications.

INTRODUCTION

The ELETTRA/SLS Multi-Bunch Feedback System is a wide band feedback correcting the positions of individual bunches, spaced 2 ns apart (Figure 1). Wide band position signals coming from button type BPMs get converted to baseband (DC-250 MHz), followed by sampling with a fast 8 bit, 500 MS/s Analog to Digital Converters (ADC). A digital filter calculates correction kicks, which are getting reconverted via 8 bit, 500 MS/s Digital to Analog Converter (DAC). For the transverse feedback, the signals are directly fed via broad band power amplifiers and strip line kickers to the beam, in the longitudinal plane, a Lower Single Side Band (LSSB) modulator mixes the signals up to the 1.25-1.5 GHz band, where they get amplified and fed to a longitudinal kicker [1] [2].

Figure 2: Digital filter structure

The digital filter (Fig. 2) consists of the ADC itself, which is followed by a first one to four demultiplexing stages. A second one to six demultiplexing reduces the data rate to approximately 20 MS/s, The six Front Panel Data Ports (FPDP) each feed a quad processor board containing TI-TMS320C6201 Digital Signal Processors (DSP). Three processors per board concurrently calculate the correction kicks, whereas one DSP takes all the data from the FPDP port and is used for on-line beam diagnostics.

The system described has been shown to work (e.g. [1]) and two systems are in routine operation on the vertical and horizontal planes at ELETTRA. A show stopper in setting up a feedback for all planes proved to be the cessation of production of the ADC and DAC boards, which were planned to be used. Following that, it was decided to launch our own development of ADC and DAC boards, at the same time trying to improve on the suitability for feedback and other accelerator applications. The main specifications of the boards are given in table 1.
Sampling Rate 200-500 MHz
Resolution 8 bits
Input Impedance 50 Ω
Coupling AC
Analog Bandwidth (3 dB) 5kHz - 500 MHz
In-band Phase Rotation < 10°
Input Level(ADC) 0 dBm
Output Level(DAC) 6 dBm
Signal/Noise + Distortion Ratio (Total Dynamic Distortion) > 40dB
External Clock Sine Wave/DECL
Clock Programmable Shift Range > 2ns, steps < 100 ps
External Trigger DECL
Total Jitter from Clock Input to Analog I/O: < 10 ps
VME interface VME64x compatible A32/D32 (base address geographic or switch selectable)
FPDP Interface ANSI/VITA 17
Single Ended TTL, 80 pin connector
Number of FPDP Ports 1 to 12
Memory Size 8 MByte

Table 1: Main ADC and DAC specifications

The ADC communicates with the main board at a 500 MS/s data rate via the LVDS bus. In the main board FPGA, the eight bit data is demultiplexed with a ration of 1 to four to produce a 32 bit wide internal data rate at 125 MHz. The data passes a Gray to Binary decoder and a 2 ways data redirector, which may send the data either to the FPDP board for further demultiplexing or the ZBT memory, which is configured as ring memory, or to both. For hardware debugging purposes, the ZBT memory can also be written via the VME interface and used to generate data streams at the FPDP ports. The FPDP board takes the 125 MS/s data from the main board and does an additional de-
multiplexing with a programmable ratio of one to five to one to twelve, which are sent out to the FPDP ports. For demultiplexing ratios in the excess of 6 an additional board is necessary purely to carry the required connectors. The board can be triggered either via a software trigger or an external DECL trigger signal. A photo of the main board is shown in figure 5.

The DAC works in the reverse manner. The FPDP board, being triggered via the Data Valid (DVALID) line of the FPDP ports, multiplexes the input data into a 32 bit 125 MS/s data stream for the main board FPGA, where it is buffered into an internal FIFO register. A START_DAC trigger (external DECL or software) launches the second one to four multiplexing stage in order to produce the 500 MS/s data for the DAC circuit. Analog to the ADC, a 2
ways data redirector is incorporated into the chip, which allows storing FPDP input into the internal RAM and even using the DAC for data playback, where a signal written into the ZBT RAM is fed to the DAC.

An important parameter determining the efficiency of any feedback application is the latency of the data throughput, which was reduced to a total of 88 ns for ADC and DAC board combined.

**BEAM TESTS**

![Vertical CBM spectrum, Cy=2](image)

**Figure 6:** Vertical coupled bunch mode spectrum, 75 mA beam current with all buckets filled, vertical chromaticity set at three times the standard chromaticity.

With laboratory testing for the ADC board completed, a first commissioning for the front end part of the transverse multi bunch feedback has been started. The system consists of the RF front end, the new ADC board used with a demultiplexing ratio of one to six connected to the six DSP board. Equally included was another new development, a four channel 500 MHz DECL clock generator/shifter. Without the DAC, the system was used as a passive diagnostic device, reading out bunch by bunch vertical position data via the diagnostics DSPs.

For testing, we used a non standard homogeneous fill with out any gap with an average current of 75 mA. Since there is no gap in the fill pattern, coupled bunch modes due to daisy chain like effects as resistive wakes and ions will show up quite clearly despite the comparatively low current. Varying the chromaticity of the ring produces a mix of combinations of these effects.

With a high chromaticity setting just below the stability threshold at three times the nominal value, the spectrum in figure 6 was obtained, showing high peaks $Q = -1, -2, -3 \ldots + Q_y$, $Q_y = 0.17$ typical of an instability dominated by resistive wakes. Lowering the vertical chromaticity further to the nominal value leads the CBM spectrum in figure 7, where resistive wall instabilities are still recognizable, but the beam motion is dominated by other effects, probably of the ion type.

**Figure 7:** Vertical coupled bunch mode spectrum, 75 mA beam current with all buckets filled, vertical chromaticity set to standard chromaticity.

**OUTLOOK**

As also the Digital to Analog Converter boards will become available in the near term, the main application for the new boards will be to commission and get into operation the bunch by bunch feedback systems for all three planes at SLS and for the longitudinal plane at ELETTRA (Two systems are in operation for now.). Extremely interesting is the strongly reduced latency of the new development in comparison to the original boards, which will allow to reduce the latency of the overall digital filter by one whole bunch circulation period (960 ns in the case of SLS), so that higher efficiency and better performance can be expected.

Another system planned now is a bunch by bunch current feedback, optimizing the behavior of the SLS top up system [3]. The feedback RF front end together with a stand alone ADC board is going to be used to read out the sum signal of a BPM pickup. This information will be used for selective refilling of empty buckets in order to have a highly controllable fill pattern.

A third application will be taking bunch by bunch data from the wide band BPM and microwave front end installed in the SLS storage ring, which will allow to measure intra bunch charge distributions for individual bunches within a multi bunch filling [4].
