Abstract

The 200MeV proton synchrotron of circumference of 9.54m is being developed for medical radiotherapy. The rf system has been carried out with a wide bandwidth of frequency sweeping from 2.0MHz to 17.8MHz. The rf cavity is designed of a compact dimension and a high acceleration gradient. The high power test of the rf system has been successfully performed and maximal acceleration gradient of 60kV/m has been achieved. The experiments with rf feedback control system tracking to the exciting current of bending magnets are being studied. In this paper, the recent progress of the rf system and test results will be presented in detail.

INTRODUCTION

The compact proton synchrotron is being developed for the medical radiotherapy [1, 2, 3]. According to the lattice design of the machine, the proton synchrotron is operated in pulse mode with the beam acceleration time of 5ms, in which the bending magnet attains 3T and the proton beam energy reaches 200MeV [4, 5]. The circumference of synchrotron is only 9.54m, so the beam acceleration system is required to have frequency sweeping from 2MHz to 17.8MHz, and maximal rf cavity voltage of 10kV, as shown in Fig. 1 [6, 7, 8]. Therefore, the key features of this rf system are the relatively wide bandwidth and the high acceleration gradient. The rf system has been designed and developed as shown in Fig. 2, and the above requirements have been successfully achieved.

RF CAVITY AND POWER AMPLIFIER

The rf cavity consists of 2 cells with gaps located in the center of each cell. There are 4 high-permeability magnetic alloy cores loaded in each cell, and the cavity length is 400mm. The impedance at the two gaps has been measured. The average value of impedance of test result and the calculation result are shown in Fig. 3. It is shown that the test result agrees with the calculation result very well. The gap capacitance is about 24pF, and the complex permeability of cores is $\mu = 1288f^{-0.81} - j3161f^{-0.81}$, where f is in MHz.

Two tetrode tubes 4CX35,000C are used to form a push-pull amplifier to drive the two cells of rf cavity in parallel, as shown in Fig. 4. All-pass network is applied to the input circuit for matching the tube's input capacitance. The parts of the all-pass network have been adjusted carefully, and SWR of tube input circuit is obtained smaller than 1.15 in the whole operation frequency range. A 2kW preamplifier T145-6346B (Thamway Co., LTD) is used to drive the main amplifier.

In order to improve the frequency response of rf system, an inductor (L_i) of 1.9 μ H is inserted between the cavity and amplifier tube. The maximal acceleration gradient of 60kV/m has been obtained.

SOLUTION OF SELF-RESONANCES

The original design of the anode rf choke for the rf system is 160μH. However during the high power test, with input power increasing, arcing occurred in the anode rf choke around frequency of 8.3MHz and 13.3MHz. The arcing is caused by the self-resonances due to the stray capacitance in the choke. So, we reduced the inductance of the rf choke from 160μH to 40μH, and found the self-resonances are removed out completely finally. Table 1 shows the frequency of self-resonances in the rf choke. Fig. 5 shows the waveform of rf cavity gap voltage with frequency sweeping from 2MHz to 18MHz without feedback. The obtained maximal gap voltage is shown in Fig. 6. It shows the rf system can stably produce much higher voltage than required in the whole operation frequency region.

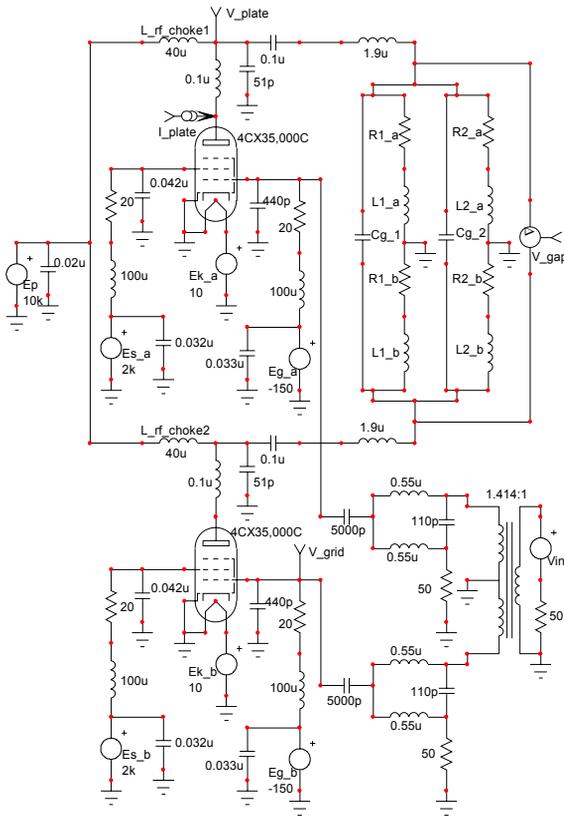

Figure 4: Circuit of rf cavity and power amplifier.

Table 1: Frequency of self-resonances in rf choke.

L(μH)	f(MHz)
160	8.3, 13.3
80	9
60	15
40	No self-resonances

RF FEEDBACK CONTROL SYSTEM

An rf feedback control system basing on a DDS signal generator has been developed as shown in Fig. 7. During the acceleration process, the rf frequency sweeps from 2MHz to 18MHz, tracking to the exciting current of bending magnet. The envelope of rf gap voltage is $5\cos(90\pi t)$ kV.

Two broadband high voltage probes for measuring gap voltage have been developed as shown in Fig. 8. The equivalent circuit of probe is shown in Fig. 9, where C1 is a coaxial capacitor. In order to reduce the effect of distributed inductance in large capacitor C2 and obtain a flat probe ratio, the capacitor C2 is divided into 6 parallel, and in each set, a capacitor of 470pF is connected with a resistor of 7.5Ohm. The design ratio is around 2500. The test result and fitting function of probe ratio is shown in Fig. 10, and the function is used in the rf control system for correction of cavity voltage.

Figure 8: Developed broadband high voltage probes for rf cavity.

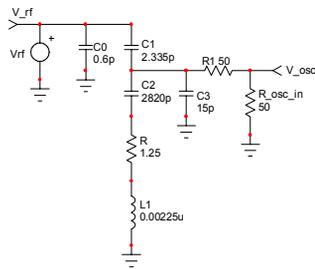

Figure 9: Circuit of broadband high voltage probe.

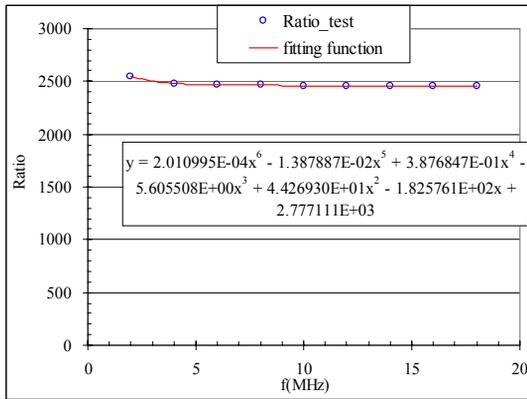

Figure 10: Test result and fitting function of probe ratio.

The experiments of rf control system have been successfully performed with feedback of gap voltage amplitude, as shown in Fig. 11. The green waveform (CH2) shows the rf cavity gap voltage with a cosine envelope and frequency sweeping from 2MHz to 18MHz tracking to the exciting current of bending magnet (CH1).

SUMMARY

The rf system for the compact proton synchrotron has

been developed. The high power test has been successfully performed to achieve the required gap voltage stably. And the experiments of rf feedback control system have been successfully carried out.
