Abstract
A quasi-classical method is developed to calculate the radiation damping of a relativistic particle in a straight, continuous focusing system. In one limiting case where the pitch angle of the particle \( \theta_p \) is much larger than the radiation opening angle \( 1/\gamma \), the radiation power spectrum is similar to synchrotron radiation and the relative damping rate of the transverse action is proportional to the relative energy loss rate. In the other limiting case where \( \theta_p \ll 1/\gamma \), the radiation is dipole in nature and the relative damping rate of the transverse action is energy-independent and is much faster than the relative energy rate. Quantum excitation to the transverse action is absent in this focusing channel. These results can be extended to bent systems provided that the focusing field dominates over the bending field.

I. INTRODUCTION
Radiation reaction including damping and quantum excitation has been studied extensively in synchrotrons and storage rings [1]. Recently, we demonstrated [2] that in a straight, continuous focusing channel, the radiation reaction is essentially different from that in a bending magnet. A fully quantum mechanical approach was used to investigate in detail the radiation reaction in the case \( \gamma \theta_p \ll 1 \) where the radiation is formed over many oscillation wavelengths. We have shown that the transverse action damps exponentially with an energy-independent damping rate, and that no quantum excitation is induced. As \( \gamma \theta_p \) becomes much larger than one, the radiation is formed in a small portion of one wavelength, which can be nearly replaced by a segment of a circle. Therefore, both the radiation spectrum and the radiation damping will be similar to that from a sequence of bending magnets. In this paper, to illustrate the smooth transition between these two limiting cases, we develop a quasi-classical method to evaluate the radiation damping rate for any \( \gamma \theta_p \) and obtain the expected results in both small and large \( \gamma \theta_p \) limits. Then we extend these findings to focusing-dominated bent systems and consider the possibility of beam cooling based on the damping effect.

II. RADIATION
Let us consider a planar focusing system that provides a continuous parabolic potential \( K \chi^2/2 \), where \( K \) is the focusing strength. A charged particle with energy \( E = \gamma mc^2 (\gamma \gg 1) \) oscillates in the transverse \( x \) direction while moving freely in the longitudinal \( z \) direction with a constant longitudinal momentum \( p_z \) in the absence of radiation. Define the pitch angle of the particle \( \theta_p = p_x / p_z \) (\( p_{x,\text{max}} \) being the maximum transverse momentum) and assume that \( \theta_p \) is always much less than one. The motion of the particle can be decomposed into two parts: a free longitudinal motion and a transverse harmonic oscillation; i.e., we have \( E \simeq E_z + E_x \), with \( E_z = \sqrt{p_z^2 c^2 + \gamma^2 m^2 c^4} \) and \( E_x = p_x^2 c^2 / 2E_z + K \chi^2/2 \).

A quantum mechanical theory of radiation and radiation reaction for such a system was given in Ref. [2]. We only need to know that \( E_x = (n + 1/2)\hbar \omega_x \), where \( n = 0, 1, 2, \ldots \) is the transverse quantum number and \( \omega_x = \sqrt{K c^2 / E_x} \) is the transverse oscillation frequency. For sufficiently large quantum number \( n \), the transverse motion is classical and the radiation can be described by classical electrodynamics provided that the typical photon energy emitted is much smaller than the energy of the particle. Thus the energy radiated per unit solid angle per unit frequency is given by

\[
\frac{d^2 E}{d\Omega d\omega} = \frac{e^2 \omega^2}{4\pi^2 c} \left| \int_{-\infty}^{\infty} \vec{n} \times (\vec{n} \times \vec{p}) e^{i\omega (t - \vec{r} / c)} \int_0^{2\pi} \sin \theta d\theta \right|^2,
\]

(1)

where \( \vec{n} \) is the unit vector from the source to the observation point, \( \vec{p} \) is the velocity and position of the particle at the retarded time \( t' \).

We can express Eq. (1) in the form of a double integral with respect to \( t_1 \) and \( t_2 \):

\[
\frac{d^2 E}{d\Omega d\omega} = \frac{e^2 \omega^2}{4\pi^2 c} \int_{-\infty}^{\infty} dt_1 \int_{-\infty}^{\infty} dt_2 \left( \vec{p}_1 \cdot \vec{p}_2 - 1 \right) e^{i \Phi_{1,2}}.
\]

(2)

where we have introduced the notation \( \vec{p}_1 = \vec{p}(t_1) \), \( \vec{p}_2 = \vec{p}(t_2) \). Going over to the new variables of integration \( t \) and \( \tau \) via the transformation \( t_1 = t - \tau / \omega_x \) and \( t_2 = t + \tau / \omega_x \), and treating the integrand in the integral with respect to \( t \) as the angular spectral distribution of the radiated power at time \( t \), we have

\[
\frac{d^2 E}{d\Omega d\omega} = \frac{e^2 \omega^2}{2\omega_0 c^2} \int_{-\infty}^{\infty} d\tau \left( \vec{p}_1 \cdot \vec{p}_2 - 1 \right) e^{i \Phi_{1,2}}.
\]

(3)

The averaged radiation power is obtained by integrating over \( d\Omega d\omega \) and then averaging over one oscillation period (indicated by \( \langle \rangle \)). In the system we consider here, it can be shown that [4]

\[
\left\langle \frac{dE}{dt} \right\rangle = \frac{2ie^2}{\pi c} \omega_x^2 \int_0^{\infty} g(\tau, \xi) e^{-i \gamma \tau / \tau^2} d\tau,
\]

(4)

where

\[
f(\tau, \xi) = 2\xi \tau (1 + \gamma^2 \theta_p^2 (1 - \sin^2 \tau / \tau^2)^2),
\]

\[
g(\tau, \xi) = J_0(u) + \gamma^2 \theta_p^2 \sin^2 \tau \left[ J_0(u) - i J_1(u) \right],
\]

\[
u = \gamma^2 \theta_p^2 \sin^2 \tau / \tau - 2 \sin 2\tau / 2, \quad \xi = \omega / 2\gamma^2 \omega_x,
\]

and \( J_v(u) \) is the Bessel function of order \( v \) (\( v = 0, 1, 2, \ldots \)).

Equation (4) is completely general for any \( \gamma \theta_p \). The contour of integration with respect to \( \tau \) must be displaced below the real axis around \( \tau = 0 \) to guarantee the vanishing radiation when the field is switched off [4]. The range of \( \tau \) that gives a significant contribution to the integral can be defined as the
The energy and the longitudinal momentum conservation require
\[ \Delta E_\omega \simeq \hbar (1 - \beta \cos \theta ) \], where \( \theta \) is the angle between the photon direction and the longitudinal direction. Writing \( \Delta \omega_\gamma \simeq -\hbar \omega_\gamma \theta_\rho^2 / 3E_\omega \), we get
\[ \Delta J_\gamma \simeq \hbar (1 - \beta \cos \theta + \theta_\rho^2 / 4 \omega_\gamma), \] which is always positive definite. Thus the transverse action always decreases after a photon emission process and the quantum excitation is absent in such a system. This result was obtained for the transverse quantum number \( n \) based on the same kinematic argument in Ref. [2].

The damping rate of transverse action \( \langle dJ_\gamma / dt \rangle \) is obtainable by replacing \( \Delta F \) in Eq. (8) with \( \Delta J_\gamma \) in Eq. (9). With the expansion \( 1 - \beta \cos \theta = 1/(2y^2) + \theta^2 / 2 \), \( \langle dJ_\gamma / dt \rangle \) can be written as \( \langle dJ_{\gamma 1} / dt \rangle + \langle dJ_{\gamma 2} / dt \rangle \), where
\[
\begin{align*}
\frac{dJ_{\gamma 1}}{dt} &= \frac{1}{\omega_\gamma} \left[ \frac{1}{2y^2} + \frac{\theta^2}{4} \right] \frac{dE}{dt}, \\
\frac{dJ_{\gamma 1}}{dt} &= \left[ \frac{2}{\omega_\gamma} \right] \int_0^{2\pi / \omega_\gamma} \int_0^\infty d\xi \int_{-\infty}^\infty dt \{ h(\tau, \xi) e^{-i \phi(\tau, \xi)} \}, \\
\rho_1 \rho_2 \int_0^\infty d\xi \int_{-\infty}^\infty dt \{ h(\tau, \xi) e^{-i \phi(\tau, \xi)} \}, \\
\end{align*}
\]
and all quantities used above are defined in Eq. (4). Similar to the calculation of the averaged radiation power, we can show \[ \langle dJ_{\gamma 1} / dt \rangle \simeq 2 \langle dJ_{\gamma 2} / dt \rangle \simeq e^2 \gamma^2 \theta_\rho^2 / 12c. \]

By using the relation \( J_\gamma / E \simeq \gamma^2 \theta_\rho^2 / 2 \omega_\gamma \), it is straightforward to obtain
\[ \frac{1}{J_\gamma} \frac{dJ_\gamma}{dt} = \frac{3}{4} E \frac{dE}{dt}, \]
which is always positive definite. Thus the transverse action always decreases after a photon emission process and the quantum excitation is absent in such a system. This result was obtained for the transverse quantum number \( n \) based on the same kinematic argument in Ref. [2].

The damping rate of transverse action \( \langle dJ_\gamma / dt \rangle \) is obtainable by replacing \( \Delta F \) in Eq. (8) with \( \Delta J_\gamma \) in Eq. (9). With the expansion \( 1 - \beta \cos \theta = 1/(2y^2) + \theta^2 / 2 \), \( \langle dJ_\gamma / dt \rangle \) can be written as \( \langle dJ_{\gamma 1} / dt \rangle + \langle dJ_{\gamma 2} / dt \rangle \), where
\[
\begin{align*}
\frac{dJ_{\gamma 1}}{dt} &= \frac{1}{\omega_\gamma} \left[ \frac{1}{2y^2} + \frac{\theta^2}{4} \right] \frac{dE}{dt}, \\
\frac{dJ_{\gamma 2}}{dt} &= \left[ \frac{2}{\omega_\gamma} \right] \int_0^{2\pi / \omega_\gamma} \int_0^\infty d\omega \int_0^\infty d\tau \{ h(\tau, \xi) e^{-i \phi(\tau, \xi)} \}, \\
\rho_1 \rho_2 \int_0^\infty d\xi \int_{-\infty}^\infty dt \{ h(\tau, \xi) e^{-i \phi(\tau, \xi)} \}, \\
\end{align*}
\]
and all quantities used above are defined in Eq. (4). Similar to the calculation of the averaged radiation power, we can show \[ \langle dJ_{\gamma 1} / dt \rangle \simeq 2 \langle dJ_{\gamma 2} / dt \rangle \simeq e^2 \gamma^2 \theta_\rho^2 / 12c. \]

By using the relation \( J_\gamma / E \simeq \gamma^2 \theta_\rho^2 / 2 \omega_\gamma \), it is straightforward to obtain
\[ \frac{1}{J_\gamma} \frac{dJ_\gamma}{dt} = \frac{3}{4} E \frac{dE}{dt}, \]
which is always positive definite. Thus the transverse action always decreases after a photon emission process and the quantum excitation is absent in such a system. This result was obtained for the transverse quantum number \( n \) based on the same kinematic argument in Ref. [2].

The damping rate of transverse action \( \langle dJ_\gamma / dt \rangle \) is obtainable by replacing \( \Delta F \) in Eq. (8) with \( \Delta J_\gamma \) in Eq. (9). With the expansion \( 1 - \beta \cos \theta = 1/(2y^2) + \theta^2 / 2 \), \( \langle dJ_\gamma / dt \rangle \) can be written as \( \langle dJ_{\gamma 1} / dt \rangle + \langle dJ_{\gamma 2} / dt \rangle \), where
\[
\begin{align*}
\frac{dJ_{\gamma 1}}{dt} &= \frac{1}{\omega_\gamma} \left[ \frac{1}{2y^2} + \frac{\theta^2}{4} \right] \frac{dE}{dt}, \\
\frac{dJ_{\gamma 1}}{dt} &= \left[ \frac{2}{\omega_\gamma} \right] \int_0^{2\pi / \omega_\gamma} \int_0^\infty d\omega \int_0^\infty d\tau \{ h(\tau, \xi) e^{-i \phi(\tau, \xi)} \}, \\
\rho_1 \rho_2 \int_0^\infty d\xi \int_{-\infty}^\infty dt \{ h(\tau, \xi) e^{-i \phi(\tau, \xi)} \}, \\
\end{align*}
\]
and all quantities used above are defined in Eq. (4). Similar to the calculation of the averaged radiation power, we can show \[ \langle dJ_{\gamma 1} / dt \rangle \simeq 2 \langle dJ_{\gamma 2} / dt \rangle \simeq e^2 \gamma^2 \theta_\rho^2 / 12c. \]

By using the relation \( J_\gamma / E \simeq \gamma^2 \theta_\rho^2 / 2 \omega_\gamma \), it is straightforward to obtain
\[ \frac{1}{J_\gamma} \frac{dJ_\gamma}{dt} = \frac{3}{4} E \frac{dE}{dt}, \]
which is always positive definite. Thus the transverse action always decreases after a photon emission process and the quantum excitation is absent in such a system. This result was obtained for the transverse quantum number \( n \) based on the same kinematic argument in Ref. [2].
where \( r_e = e^2/mc^2 \) is the classical electron radius. We see that the transverse action damps exponentially with an energy-independent damping constant \( \Gamma_c = 2r_eK/3mc \). An identical result for the transverse quantum number \( n \) was obtained in Ref. [2] for the "undulator regime" where \( \gamma \theta_p \ll 1 \). We also notice that the relative damping rate of the transverse action is much faster than the relative energy loss rate in this regime since

\[
\Gamma_c = \frac{1}{J^2} \left( \frac{dJ}{dt} \right) \gg \frac{1}{E} \left( \frac{dE}{dt} \right) = \frac{\Gamma_r}{2} \gamma^2 \theta_p^2 .
\]

We have shown that the radiation damping in a straight, continuous focusing channel is fundamentally different from that in a bending magnet. In the longitudinal direction the particle recoils against the emitted photon to conserve the longitudinal momentum between the two particles. However, in the transverse direction, the existence of the focusing force destroys the momentum balance and suppresses the direct recoil effect. As a result, the radiation reaction is not opposite to the photon emission direction, but always has a component pointing towards the focusing axis.

IV. FOCUSING-DOMINATED SYSTEMS

So far we have assumed that the focusing system is straight. In fact, the above discussion can be extended to bent systems under certain conditions. Consider a bent system with a constant radius \( \rho \). A highly relativistic particle of energy \( E \) being bent by a uniform magnetic field, \( B = E/\rho c \), radiates at the rate \( \langle dE/dt \rangle = 2r_eE^4/(3mc^6\rho^2) \). Thus the characteristic damping (or anti-damping) rate in all three degrees of freedom due to the bending is \( \Gamma_b \sim \langle dE/dt \rangle / E = 2r_e\gamma^2 \theta_p ^2/(3\rho^2) \).

In addition, the particle radiates while executing rapid betatron oscillations around the circular bent trajectory due to the focusing field. If the bending is adiabatic and the particle’s pitch angle relative to the ideal orbit is small compared with \( 1/\gamma \), the transverse damping rate due to betatron oscillations can then be approximated by \( \Gamma_r = 2r_eK/3mc \), as discussed in the previous section. Taking the ratio of these two rates, we obtain:

\[
\frac{\Gamma_b}{\Gamma_r} = \frac{\tilde{x}_\beta^2}{(\rho/\gamma)^2}
\]

where \( \tilde{x}_\beta = \lambda_\beta/2\pi = \sqrt{E/K} = c/\omega_\beta \) is the reduced betatron wavelength. Equation (16) shows that if \( \rho/\gamma \gg \tilde{x}_\beta \), the transverse damping due to local oscillations is much stronger than that from the global bending of the trajectory. Since \( \rho/\gamma = E/\gamma e c B = mc/e B \), we conclude that in a system that satisfies \( mc/e B \gg \sqrt{E/K} \) or \( K \gg \gamma e^2 B^2/m \), the radiation damping is dominated by the focusing field.

To illustrate the choice of parameters for such a system, we consider a numerical example: a focusing-dominated low energy electron ring. Let us assume that the radius of the ring is \( \rho = 33 \) and that \( E = 0.1 \text{GeV} \). Electrons circulate around the ring. A rather weak magnetic field \( B = 0.01 \text{T} \) is required to confine the particles on the ideal circular trajectory. Suppose along the ideal trajectory, the electrons are continuously focused with the focusing strength \( K = 30 \text{GeV/m}^2 \), so the reduced betatron wavelength \( \tilde{x}_\beta \) is about 5.8cm and \( \rho/\gamma \) is about 17cm. From Eq. (16), we see that the transverse damping rate due to the focusing field is about nine times as fast as the characteristic damping (or anti-damping) rate from the bending field.

In a straight system, quantum excitation is absent because the transverse action must decrease after every photon emission to satisfy the kinematic constraints. In a bent system, the dispersion effect may introduce a random fluctuation of the transverse action. Nevertheless, because of the discreteness of the transverse action, there seems to exist a set of consistent conditions under which quantum excitation is prohibited even in a dispersive system [2].

V. CONCLUSION

The basic results obtained here apply to straight or bent, focusing-dominated systems. The excitation-free, asymmetric radiation damping in such systems is the direct consequence of the kinematic requirements and does not depend on the various approximations used above. There may be interesting applications of this phenomenon in beam cooling. For example, in a sufficiently low-energy, focusing-dominated electron ring, this damping effect could perhaps be utilized to obtain ultra-cool beams in transverse phase space without much energy loss. Since the system is free of radiation excitation, the actual equilibrium beam emittance will depend upon the details of the application considered.
