# MINIMIZING THE ENERGY SPREAD WITHIN A SINGLE BUNCH BY SHAPING ITS CHARGE DISTRIBUTION* <br> Gregory A. Loew and J. W. Wang <br> Stanford Linear Accelerator Center <br> Stanford University, Stanford, California 94305 

## Introduction

When electrons or positrons in a bunch pass through the periodic structure of a linear accelerator, they leave behind them energy in the form of longitudinal wake fields. The wakefields thus induced by early particles in a bunch offsel the energy of later particles. For a linear collider, the energy spread introduced within the bunches by this beam loading effect must be minimized because it limits the degree to which the particles can be focused to a small spot due to chromatic effects in the final focus system. ${ }^{\dagger}$ For example, for the SLC, the maximum allowable energy spread is $\pm 0.5 \%$.

It has been known for some time that partial compensation of the longitudinal wake field effects can be obtained for any bunch by placing it ahead of the accelerating crest (in space), thereby letting the positive rising sinusoidal field offset the negative beam loading field. ${ }^{1}$ The work presented in this paper shows that it is possible to obtain complete compensation, i.e., to reduce the energy spread essentially to zero by properly shaping the longitudinal charge distribution of the bunch and by placing it at the correct position on the wave.

## Optimizing the Bunch Shape

The energy gained by a single particle riding at an angle $\theta_{1}$ with respect to the crest of a traveling wave of accelerating gradient $E_{0}$ over a length $L$ is

$$
\begin{equation*}
V=E_{0} L \cos \theta_{1} \tag{1}
\end{equation*}
$$

In the case of a bunch consisting of many particles, this energy is modified by the presence of the wake fields left by particles ahead of $\theta_{1}$. For the examples worked out in this paper, we will use the SLAC constant-gradient structure although the technique should be applicable to any structure for which the longitudinal wake function is known. This wake function, $w_{L}(\theta)$, is defined as the voltage excited by a unit charge traversing the structure. It is shown in Fig. 1 as calculated for a single average cavity of length $d(d=3.5 \mathrm{~cm})$ of the SLAC constant-gradient structure. ${ }^{2}$ At the cost of an error estimated to be on the order of $5 \%$, we can neglect the fact that the actual cavitics differ in iris diameter from this average cavity by about $\pm 15 \%$. We can then obtain the function $W_{L}$ for the entire accelerator by simply multiplying $w_{L}(\theta)$ by $N$, the number of cavities $(L / d)$. With these definitions and a bunch charge distribution $f\left(\theta^{\prime}\right)$ as illustrated in Fig. 2, Eq. (1) now becomes:

$$
\begin{equation*}
V\left(\theta_{1}\right)=V_{0} \cos \theta_{1}-\int_{0}^{\left(\theta_{0}-\theta_{1}\right)} f\left(\theta^{\prime}\right) W_{L}\left(\theta_{0}-\theta_{1}-\theta^{\prime}\right) d \theta^{\prime} \tag{2}
\end{equation*}
$$

where $V_{0}=E_{0} L, \theta_{0}$ is the position of the head of the bunch with respect to the wave and $\theta^{\prime}$, the coordinate within the

[^0]

Fig. 1. Longitudinal wake function $w_{L}(\theta)$ for single average cavity of SLAC constant-gradient structure.

Fig. 2. Definitions of phase angles showing position of bunch with respect to accelerating wave. The charge distribution is $f\left(\theta^{\prime}\right)$ and the maximum energy gain is $V_{0}$.
bunch, is made to vary from 0 (the head of the bunch) to $\theta_{0}-\theta_{1}$ (the position where we want to know the net energy).

In order to reduce the energy spread within the bunch to zero, we must make $V\left(\theta_{1}\right)$ independent of $\theta_{1}$. This requires that

$$
\begin{equation*}
\frac{\partial V\left(\theta_{1}\right)}{\partial \theta_{1}}=0 \tag{3}
\end{equation*}
$$

By taking the partial derivative of Eq . (2) with respect to $\theta_{1}$ and setting it to zero, we get:

$$
\begin{gathered}
-V_{0} \sin \theta_{1}-\int_{0}^{\left(\theta_{0}-\theta_{1}\right)} f\left(\theta^{\prime}\right) \frac{\partial W_{L}}{\partial \theta_{1}}\left(\theta_{0}-\theta_{1}-\theta^{\prime}\right) \\
d \theta^{\prime}+f\left(\theta_{0}-\theta_{1}\right) W_{L}(0)=0
\end{gathered}
$$

or
$f\left(\theta_{0}-\theta_{1}\right)=\frac{V_{0}}{W_{L}(0)} \sin \theta_{1}+\int_{0}^{\left(\theta_{0}-\theta_{1}\right)} \frac{f\left(\theta^{\prime}\right) \frac{\partial W_{L}}{\partial \theta_{1}}\left(\theta_{0}-\theta_{1}-\theta^{\prime}\right)}{W_{L}(0)} d \theta^{\prime}$.
Letting $\theta_{0}-\theta_{1}=x$ where $x \geq \theta^{\prime}$, Eq. (4) becomes:

$$
\begin{equation*}
f(x)=\frac{V_{0}}{W_{L}(0)} \sin \left(\theta_{0}-x\right)-\int_{0}^{x} \frac{\frac{\partial W_{L}}{\partial x}\left(x-\theta^{\prime}\right) f\left(\theta^{\prime}\right)}{W_{L}(0)} d \theta^{\prime} \tag{5}
\end{equation*}
$$

which is a Volterra integral equation of the second kind. This equation can be solved digitally through a multi-step method using Day's starting procedure in conjunction with Simpson's rule and the three-eighths rule. ${ }^{3}$ The wake function can be fitted with a polynomial so as to be represented by an analytical expression.

Figures 3 and 4 give results for several examples. These examples were all worked out for a no-load energy $V_{0}$ of 54.75 GeV , an accelerator length $L$ of 960 sections, each with 86 cavities (i.e., $L=2890 \mathrm{~m}, N=82,560$ cavities) and a bunch of integrated charge $5 \times 10^{10} e$. The value of $V_{0}$ was chosen so as to yield a final beam energy just over 50 GeV . Figure 3 shows six different bunch shapes with the corresponding $\theta_{0}$ 's (positions of the head with respect to the wave) required to give essentially zero energy spread. The head of the bunch is on the left (zeroabscissa) and the tail defined as the point where an integrated

Fig. 3. Bunch shape, i.e. particle distribution as a function of phase angle which leads to negligible spectrum width, for various values of $\theta_{0}$. The point marked " $T$ " indicates where the integrated charge in the bunch reaches $5 \times 10^{10} e$.
charge of $5 \times 10^{10} e$ is reached, is at the abscissa corresponding to the letter " $T$ " on each curve. An interesting aspect of these curves is that if the bunches are extended beyond the " $T$ " points as shown, the energy spread continues to be zero even though the charge in the extended bunch is greater than $5 \times$ $10^{10} e$. The end points on the individual curves give the limits of how far one can go. The curve for $\theta_{0}=13^{\circ}$ has no $T$ because the integral under it does not quite reach $5 \times 10^{10}$ particles: its charge is $3.96 \times 10^{10}$ e. Figure 4 gives the respective energies of the bunches of Fig. 3 (except for the $\theta_{0}=13^{\circ}$ case) as a function of angular position.

२

Fig. 4. Particle energy along bunches of Fig. 3 as a function of phase angle.
Table 1 gives a summary of the average energies $(\bar{E})$ and spectral qualities [( $\left.E_{m a x}-E_{m i n}\right) / \bar{E}$ and the fractional standard deviation $\left.\sigma_{E} / E\right]$ for the cases shown in Figs. 3 and 4.

Table 1
(All cases for $5 \times 10^{10}$ particles.)

| $\theta_{0}$ <br> (degrees) | $\bar{E}$ <br> $(\mathrm{GeV})$ | $\left(E_{\max }-E_{\min }\right) / \bar{E}$ <br> $(\%)$ | $\sigma_{E} / \bar{E}$ <br> $(\%)$ |
| :---: | :---: | :---: | :---: |
| 26 | 49.210 | 0.008 | 0.003 |
| 23 | 50.399 | 0.009 | 0.003 |
| 20 | 51.450 | 0.010 | 0.003 |
| 17 | 52.360 | 0.014 | 0.004 |
| 15.5 | 52.755 | 0.010 | 0.004 |
| Truncated <br> Gaussian <br> 15.5 | 52.809 | 0.14 | 0.038 |
| Ganssian <br> $\left(\sigma_{2}\right)$ <br> 20 | 52.795 | 3.5 | 0.352 |
|  |  |  |  |

The sixth example, shown also for $\theta_{0}=15.5^{\circ}$, is that of a truncated Gaussian fitted to the shape of the "ideal" $\theta_{0}=15.5^{\circ}$ case. It has a $\sigma_{z}$ of $9^{\circ}$ but is truncated at $\pm 7.5^{\circ}$. These results all compare extremely favoarably with the energy spread $\sigma_{E} / E$ of $0.35 \%$ which one obtains for a Gaussian bunch of $5 \times 10^{10} \mathrm{e}$ with a length $6 \sigma_{z}$, a $\sigma_{z}$ of $4^{\circ}$ and a $\theta_{0}$ of $20^{\circ}$ (the seventh example in Table 1), or for that matter, for the same bunch with charge reduced to $5 \times 10^{8} e$. The energy spectra for all the above cases are illustrated in Fig. 5. Note that the examples of Table 1 are so narrow in energy that they can only be represented by a line.

## Discussion

If we rewrite Eq. (5) in terms of the gradient $E_{0}$ instead of the total energy $V_{0}$, it becomes:

$$
\begin{equation*}
f(x)=\frac{E_{0} d}{w_{L}(0)} \sin \left(\theta_{0}-x\right)-\int_{0}^{x} \frac{\frac{\partial w_{L}}{\partial x}\left(x-\theta^{\prime}\right)}{w_{L}(0)} f\left(\theta^{\prime}\right) d \theta^{\prime} \tag{6}
\end{equation*}
$$

We see that for a structure with a given $w_{L}(\theta)$, once the gradient $E_{0}$ and the angular position $\theta_{0}$ of the head are chosen, the shape is fixed by Eq. (6) and is independent of the total energy $V_{0}$ and length $L$. For a given gradient $E_{0}, f(\theta)$ starts at a higher value as $\theta_{0}$ is made larger since

Fig. 5. Energy spectra for the examples of Table 1 with $5 \times$ $10^{10} e$ (left-hand scale) and for the Gaussian bunch with $5 \times$ $10^{8} e$ (right-hand scale).

$$
\begin{equation*}
f(0)=\frac{E_{0} d}{w_{L}(0)} \sin \theta_{0} \tag{7}
\end{equation*}
$$

as shown in Fig. 3. Clearly, the more charge one wants, the bigher gradient one needs, or the farther ahead of crest one must place the head.

## Tolerances

To get a feeling for allowable tolerances, it is interesting to calculate the effect of changes in injection angle ( $\theta_{0}$ ) or bunch charge on $\bar{E}$ and $\sigma_{E} / \bar{E}$, assuming constant bunch shape. Table 2 shows the effect of varying $\theta_{0}$ while keeping the total charge of the bunch equal to $5 \times 10^{10} \mathrm{e}$ in the case of the truncated Gaussian bunch discussed earlier.

Table 2. Truncated Gaussian bunch. $\left(\theta_{\text {lotal }}=15^{\circ}, \quad \sigma=9^{\circ}, \quad 5 \times 10^{10} e\right)$

| $\theta_{0}$ <br> (degrees) | $\bar{E}$ <br> $(\mathrm{GeV})$ | $\left(E_{m a x}-E_{\text {min }}\right) / \bar{E}$ <br> $(\%)$ | $\sigma_{E} / \bar{E}$ <br> $(\%)$ |
| :---: | :---: | :---: | :---: |
| 11.5 | 53.210 | 1.78 | 0.51 |
| 12.5 | 53.135 | 1.31 | 0.38 |
| 13.5 | 53.043 | 0.84 | 0.26 |
| 14.5 | 52.934 | 0.38 | 0.13 |
| 15.5 | 52.809 | 0.14 | 0.038 |
| 16.5 | 52.668 | 0.55 | 0.14 |
| 17.5 | 52.510 | 1.02 | 0.26 |
| 18.5 | 52.335 | 1.50 | 0.39 |
| 19.5 | 52.145 | 1.90 | 0.52 |

Table 3 shows the effect of changing the bunch charge while keeping its shape and $\theta_{0}$ constant.

Table 3. Truncated Gaussian bunch.

$$
\left(\theta_{\text {iotal }}=15^{\circ}, \quad \sigma=9^{\circ}, \quad \theta_{0}=15.5^{\circ}\right)
$$

| Bunch Charge <br> $\left(\times 10^{10} e\right)$ | $\bar{E}$ <br> $(\mathrm{GeV})$ | $\left(E_{\max }-E_{\min }\right) / \bar{E}$ <br> $(\%)$ | $\sigma_{E} / \bar{E}$ <br> $(\%)$ |
| :---: | :---: | :---: | :---: |
| 3 | 53.314 | 1.52 | 0.43 |
| 3.5 | 53.187 | 1.12 | 0.33 |
| 4 | 53.061 | 0.81 | 0.23 |
| 4.5 | 52.935 | 0.45 | 0.12 |
| 5 | 52.809 | 0.14 | 0.038 |
| 5.5 | 52.683 | 0.27 | 0.10 |
| 6 | 52.557 | 0.64 | 0.21 |
| 6.5 | 52.431 | 1.00 | 0.31 |
| 7 | 52.305 | 1.36 | 0.42 |

The variations of $\sigma_{E} / \bar{E}$ in both tables are close to hyperbolic.

## Conclusions

We have shown in this paper that it is theoretically possible to find bunch shapes for the SLC which yield $5 \times 10^{10}$ or more particles within negligible energy spread at the end of the linear accelerator. As it turns out, these shapes depend only on the linac energy gradient and the angle at which the head of the bunch is placed with respect to the accelerating wave, and are independent of the total energy or length of the accelerator. Excursions away from this angle in parts of the linac, designed to cause Landau damping of the transverse wake field effect, are of course permissible as long as overall "phase closure" to preserve the desired average $\theta_{0}$ is accomplished. Some of these theoretical bunch shapes are not too different from shapes that ought to be realizable from injectors or damping rings. How to realize them exactly is not the subject of this paper.
